Haverford College Department of Physics

(Dated: March 8, 2024)

No Collaborators. I have two python files.

PHYS_304_HW5_5.13_Xiyue_Shen.py file is the Quantum harmonic oscillator problem, numbered as 5.13 in the textbook.

PHYS_304_HW5_Simpson code up_Xiyue_Shen.py is the file for in-class free-choice integration exercise

1. SIMPSON'S METHOD

1.1. Equation Setup

In this problem, I aim to use Simpson's method to examine the integral. Simpson's method chooses three points and finds the equation of a quadratic through those points. The basic idea is that suppose we have three points: $f(a)$, $f(b)$, and the middle point $f(m)$. Then, we find a quadratic function that goes through the same points. We only need to integrate the quadratic over the interval for the interval. It turns out that the integral would be,

$$\frac{b-a}{6}(f(a) + 4f(m) + f(b)) \quad (1)$$

A general form based on Simpson's method would be,

$$\frac{1}{3}h[f(a) + f(b) + 4 \sum_{\text{odd } k} f(a+kh) + 2 \sum_{\text{even } k} f(a+kh)] \quad (2)$$

Based on this method, I choose my function as,

$$x^3 + 2x^2 \quad (3)$$

According to calculus, the exact integral would be,

$$\frac{1}{4}x^4 + \frac{2}{3}x^3 \quad (4)$$

1.2. Pseudocode

The basic idea here is that we use both Simpson's and the normal calculus methods and then compare them.

As always, the first thing to do is import all necessary libraries. Then, we define the Simpson method by employing some loops to achieve alternating even and odd summation as shown in equation 2. Then we define our function $x^3 + 2x^2$. After this, we set several upper limits and run a loop to perform integration over different ranges. We collect the data and compare the exact value using the calculus method. Figure 1 shows complete logic for the code.

```
Simpson's method
- Define Simpson's integration:
  def simpson(a, b, f, N):
    if N % 2 == 1:
      print("error")
    h = (b-a)/N
    S = (f(a)+f(b)) * h/3
    - After defining stepsize and the first term as shown by equation (5.9) in the textbook, we're left with  $4 \sum_{\text{odd}} f(a+kh) + 2 \sum_{\text{even}} f(a+kh)$ . We can use a loop for this.
      for i in range(1, N, 2):
        S += 4 * f(a+ih) * h
      for i in range(2, N, 2):
        S += 2 * f(a+ih) * h
    return S * h/3

- Then we proceed to our chosen function and define it.
  def f(x):
    return x^3 + 2x^2

- Set lower/upper bounds and then apply Simpson's rule.
  up = np.arange(0, 10, 0.01)
  N = 10
  solution = np.zeros_like(up)
  for i in range(len(up)):
    solution[i] = simpson(up[i], up[i+1], f, N) # integration

- Define the normal way to calculate integral and make plots.
  plt.subplot(1, 2, 1)
  plt.plot(up, solution)
  plt.plot(up, 1/4 * up^4 + 2/3 * up^3)
  plt.subplot(1, 2, 2)
  plt.plot(up, error)
  plt.show()
```

FIG. 1: [Simpson method pseudocode]

1.3. Result

Figure 2 shows the result we get using the Simpson (blue curve) and normal calculus methods (orange curve). The orange curve and blue curve cover each other, indicating a very good approximation of the Simpson method. The right plot shows the error based on a log scale, which is quite tiny on the 10^{-13} scale.

1.4. Conclusion

By setting, Simpson's method employs quadratic to make approximation. If our choice happened to be a quadratic function, then the method should show a very good fit. As shown in our plots, the error is very tiny, indicating an accurate approximation.

2. QUANTUM HARMONIC OSCILLATOR

2.1. Hermite Polynomials

In this problem, we are given a wave function involving energy state, carried by the denominator and the Hermite function. In part a, we will make a plot of the Hermit function, which is described as,

$$H_{n+1}(x) = 2xH_n(x) - 2nH_{n-1}(x) \quad (5)$$

with $H_0(x) = 1$ and $H_1(x) = 2x$.

```

Quantum Harmonic Oscillator
a). - Define Hermite polynomials
    def Hn(x):
        - Use if condition incorporating initial conditions
        if n==0:
            H0(x)=1
        elif n==1:
            H1(x)=2x
        - Rewrite the function a bit to generate Hn(x):
        else:
            2xHn-1(x) - 2(n-1)Hn-2(x)
        - Generate a array of x values:
        x = np.linspace(-4,4,100)
        - Set up a loop and calculate the wavefunction for each value of n
        for i in range(n+1):
            wavefunction = 1/sqrt(2^n * n! * pi) * e^(-x^2/2) * Hn(x)
        - Make a plot in the loop:
            plt.plot(x, wavefunction, label="Hn")
        - Modify the plot:
            plt.xlabel
            plt.ylabel
            plt.legend()
            plt.show()

```

FIG. 3: [Pseudocode for part a]

Figure 3 shows the Pseudocode for part a. When defining the Hermite polynomials, I use an if condition to set up the first two orders of polynomials. Then, the loop is used to evaluate the first four orders from $n = 0$ to $n = 3$. The plot is shown in Figure 4. Based on the plot, we observe that even and odd order gives alternating symmetrical properties around $x = 0$. This is an essential polynomial that can be used to create symmetries when encountering various potential walls.

FIG. 4: [First 4 order of Hermite Polynomials]

2.2. 30th Polynomials

We use the code in the previous part and eliminate the loop part for this part. Set $n = 30$, then do the evaluation, as shown in Figure 5

```

b). - Create a new vector of H. and call it a different name:
    H_vector2 = np.vectorize(H)
    - Similarly, create an array for x and a new figure for this plot
    x = np.linspace(-10,10,n) # n would be # of sample points
    plt.figure()
    - Set n=30 and calculate the wavefunction:
    n=30
    wavefunction = ... # use the same function in part a
    plt.plot(x, wavefunction)
    - Modify the plot
    plt.xlabel
    plt.ylabel
    plt.legend
    plt.show()

```

FIG. 5: [Pseudocode for part b]

And as expected, there will be 31 peaks as shown in figure 6.

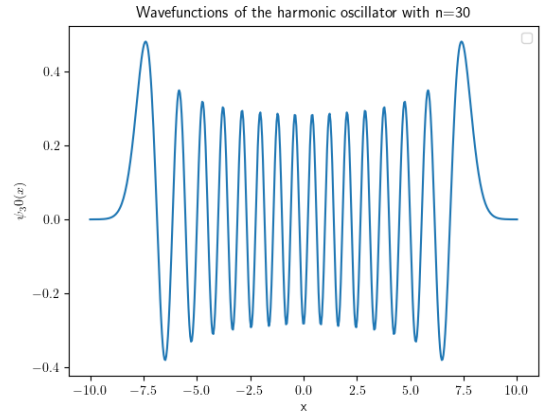

FIG. 6: [30th Hermite Polynomial]

2.3. Uncertainty approximation

As defined in Statistical mechanics and quantum mechanics, the expectation value is defined as,

$$\langle a \rangle = \int_{-\infty}^{\infty} a |\psi_n^2(x)| dx \quad (6)$$

In this case, we are given the position. The uncertainty of position is,

$$\langle x^2 \rangle = \int_{-\infty}^{\infty} x^2 |\psi_n^2(x)| dx \quad (7)$$

This integral goes from negative infinity to positive infinity. I used $x = \tan z$ and $dx = \frac{dz}{\cos^2 z}$ to transform the integral from infinity to $-\pi/2$ and $\pi/2$. I use the Gaussian Quadrature to do the integral, which is defined in the book's online resource.

```

c>
- Define our wavefunction
  Def wavefunction(h, x):
    Return 1/sqrt(n! * h) * e^(-x^2/h) * H_n(x)

- Define a new function which transform the infinite limits to specific values:
  Def wavefunctionc(z, h):
    Return 1/cos^2(z) * 1/sqrt(n! * h) * e^(-tan^2(z)/h) * H_n(tan(z))

- Import Gaussian Quadrature and assign our weights and sample points, and upper / lower limits:
  b = np.pi/2
  a = -np.pi/2
  N = 100
  x, w = gaussxwab(N, a, b)

- Start our integral by setting an initial value and a loop:
  n = 5
  s = 0.0 # set our integral to zero for start
  for i in range(N):
    s += w[i] * wavefunctionc(x[i], n)

- Get the uncertainty
  print(np.sqrt(s))

```

FIG. 7: [Uncertainty Approximation Pseudocode]

And I got 2.345 after taking square root of it, which agrees with the expected value.

$\sqrt{\langle x^2 \rangle}$ is also called a root-mean-square deviation, which is a measure of accuracy. It also help define the width of the distribution.

2.4. Physics context

This is a one-dimensional quantum harmonic oscillator. Given a random potential around a stable equilibrium point, we can set up a Hamiltonian of the particle by,

$$\hat{H} = \frac{\hat{p}^2}{2m} + \frac{1}{2}k\hat{x}^2 \quad (8)$$

The quantities with a hat above are the operators that are used a lot in quantum mechanics. \hat{p} is the momentum operator and \hat{x} is the position operator. Then we solve the Schrödinger equation defined as,

$$\hat{H}|\Psi\rangle = E|\Psi\rangle \quad (9)$$

where E is a real number showing energy. $|\Psi\rangle$ denotes the eigenstate given a specific eigenenergy. The ψ_n given in the problem is the wavefunction formula after going through the above steps.

3. SURVEY

I spent roughly 6 hours on this homework. I'm now more familiar with integration rules such as the Simpson method and Gaussian quadrature. I like the Quantum Harmonic Oscillator problem since it provides many insights into quantum mechanics. And I used tan to do the integral, which is a good practice. I think this set is about the right length.

4. UNGRADED PART

I have done all of the required and ungraded work.
